

CHEETAH: Modeling Starspots from Kepler Lightcurves

Michael A. Thomas

advised by

Adam Finkelstein & Lucianne Walkowicz

What are starspots?

- Cooler areas on the “surface” (photosphere) of a star
- Caused by internal magnetic field penetrating surface
- Solar activity (e.g. flares) tends to occur at or near spots
- Internal magnetic fields of stars not fully understood
- In general, most stellar data comes from the Sun
- Starspots could provide info about MF of other stars

Strassmeier 2009, “Starspots,” *Astron Astrophys Rev*

Kepler Data

- Stars (except Sun) generally too far away to see spots
- Kepler measures light intensity of many stars
- Brief periodic dimming used to infer planet revolution
- Gradual variation (lightcurve) used to infer spots

Walkowicz 2012 (see references)

Eker Model

- Assume circular spots
- Integrate specific intensity over visible area
- Gives “loss of light” due to spot
- Parameters:
 - Stellar inclination
 - Spot radius, latitude, longitude
 - Spot contrast, limb-darkening coefficients (fixed)

Single Spot Fitting

Algorithms used:

- Levenberg-Marquardt (LM) algorithm – numerical optimization for nonlinear least squares problems
- K-means – simple clustering algorithm

Procedure:

choose evenly spaced initial points throughout parameter space

for each point in initial points:

run LM for small number `initsteps` of iterations

cluster results into `nclusters` using K-means

select point with lowest sum squared error (SSE) from each cluster

for each point in reduced list:

run LM algorithm to convergence

sort output points by SSE, find

keep all points with $SSE < \text{threshratio} * \text{best SSE}$

(`initsteps`=20, `nclusters`=20, `threshratio`=2 seems to work well)

Multi-Spot Fitting

Sequential fitting:

- fit as single spot curve to get inclination and first spot
- for each additional spot:

 - subtract generated lightcurve from data, fit with fixed inclination

Simultaneous fitting:

- fit with LM allowing inclination and all spot params to vary simultaneously

“Ratchet” fitting:

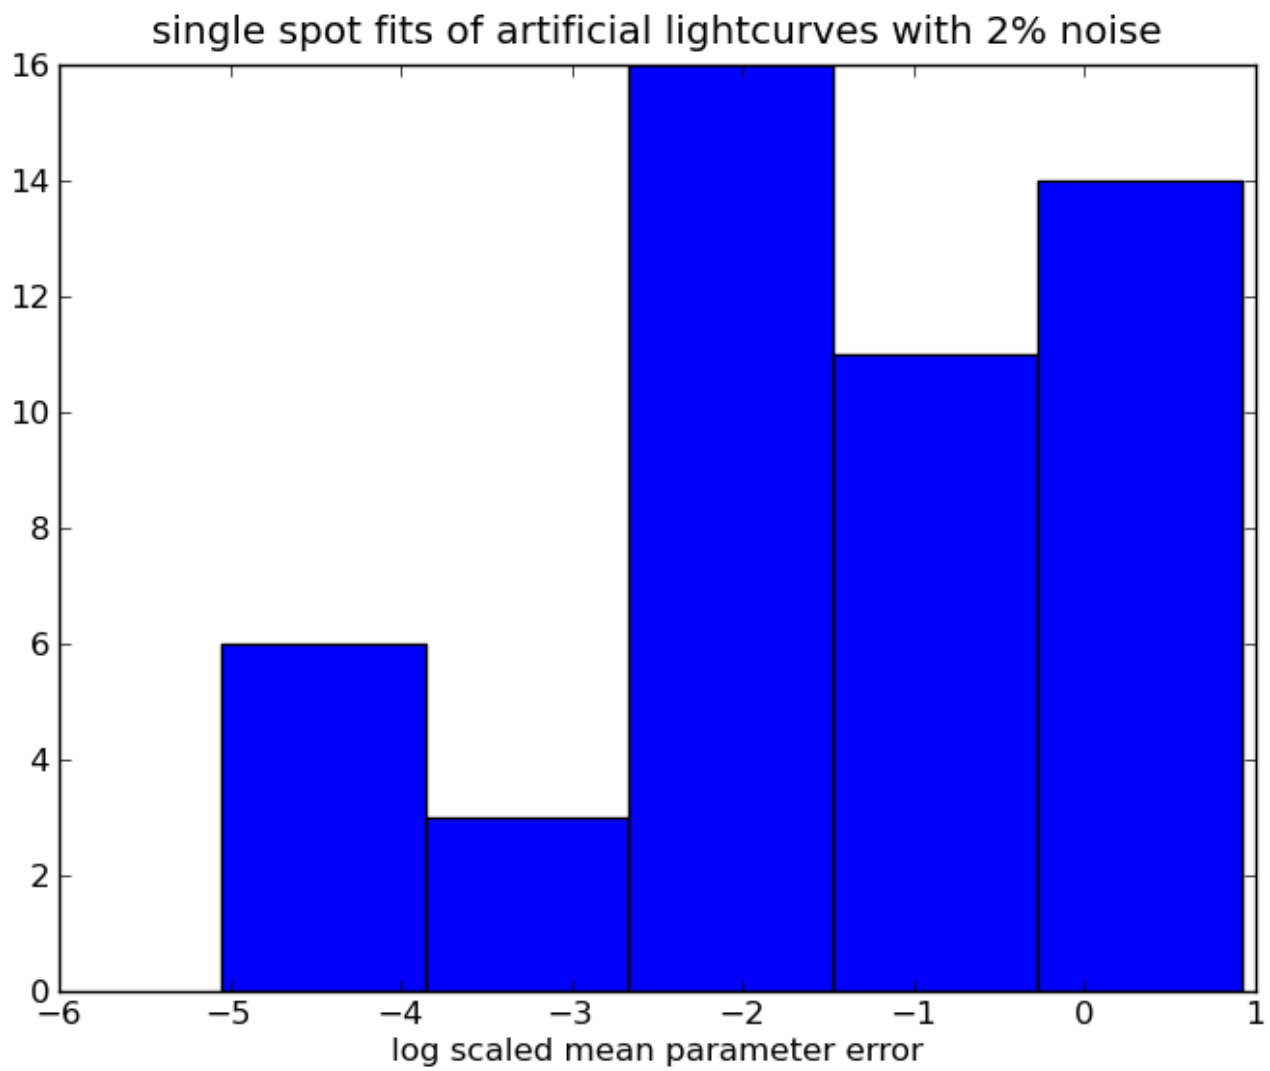

- fit first and second spot sequentially

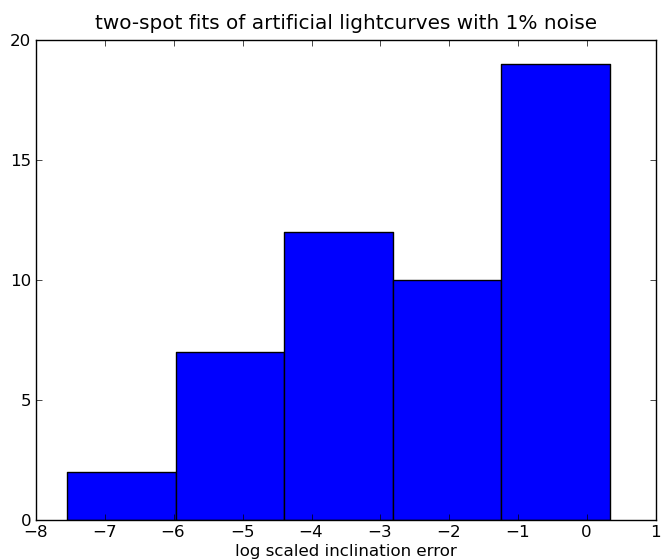

- use sequential fit output as initial points for simultaneous 2-spot fit

- for each additional spot:

 - subtract generated lightcurve from data, fit next spot sequentially

 - use output as initial points for simultaneous n -spot fit
